Cutting Fluids - WXPT202-XX01XEN-E2

Objective 4: Describe the Three Main Types of Cutting Oil

Oil-Based Cutting Fluids

Oil-based cutting fluids have been used in metal cutting since the dawn of modern machining.

Oil was mainly used for its lubricating properties, and has little or no cooling ability.

eLearning Course: MXPT202

Amatrol's Principles of Coolants and Oils eLearning courseware (MXPT202) introduces the fundamentals of the major types of coolants and oils used in manufacturing. This CNC machining training course covers oil-based and chemical-based cutting fluid, gases, and machine lubricants and oils, and focuses on the properties, purpose, application, and safety issues of each type of CNC coolant and oil.

Coolants and Oils

How Does Heat and Friction Affect Machining? How Does Coolant Help?

Heat is produced when energy is transferred from one object to another, creating a difference in temperature. In a car, for example, heat is created by friction that is produced as the pistons rub against the engine block. A car needs oil and coolant to run properly, because its engine is made up of metal components that rub together. This motion causes friction, and a by-product of friction is heat. If there was no coolant or lubricant in an engine, its parts would get hot and eventually the engine would overheat. The parts could even get hot enough to melt together, stopping the engine altogether.

Just like the car, heat in machining is created by friction that occurs when the machine's internal components rub together, or when a workpiece is being machined. When machining a workpiece, heat is caused by several factors. These factors include cutting speed, feed rate, cutting method, workpiece material, cutting operation, and depth of cut. Some cutting fluids work better, depending on which machining operation is being performed.
